Abstract
Background: Dacryocystitis is an infection and inflammation of the lacrimal sac and most common cause of ocular morbidity in India. It’s accounting for 87.1% of epiphora and causes social discomfort due to continuous watering from the eyes. It is more common in Whites than in Negros and more common in India as being tropical country. It has higher incidence among lower socioeconomic status.
Objective: To find out the occurrence of Dacryocystitis in patients belonging to various socio-economic groups and to correlate Dacryocystitis with socio-economic status.
Material & Methods: The present study is a cross-sectional hospital based study which performed during the months of June and September, 2014 in the department of Ophthalmology of ACPM Medical College, Dhule, and Maharashtra, India.
Results: Maximum number of cases of chronic Dacryocystitis belongs to the seventh decade of life. Chronic Dacryocystitis affected females predominantly. Chronic Dacryocystitis were observed in majority of patients belongs to class V & III socioeconomic status of modified B.G. Prasad Classification, and observed more in wage traders followed by farmers.
Conclusion: Most of the people consider watering from eyes as minor discomfort and avoid themselves from presenting to ophthalmologist as they are unaware of the deleterious complication. So the present study was taken up in Dhule district to create awareness of morbid condition. It’s early diagnosis and treatment is always warranted to avoid complication and need for surgical intervention.

Keywords: Chronic Dacryocystitis, Epidemiology, Socioeconomic.

Introduction
Dacryocystitis is an inflammation and infection of lacrimal sac located between the medial canthus of the eye and nose. It is an important cause of ocular morbidity in India1. Both eyes may be affected. The disease occurs as an isolated incident (acute) or ongoing (chronic) form2.

Chronic Dacryocystitis is commonly encountered by an ophthalmologist accounting for 87.1% of epiphora, which causes social embarrassment due to chronic watering from eyes3. It commonly affects females over 40 years of age with peak incidence in 60 to 70 years4. It is more common in Whites than in Negros and more common in India as being tropical country. It has higher incidence among people of lower socioeconomic status4.

It is usually caused by partial or complete obstruction in lacrimal sac or within nasolacrimal duct. The causes of acquired obstruction are infection, inflammation, neoplasms and trauma5. Patient with chronic Dacryocystitis may remain asymptomatic or have watering, discharge from the eye and swelling at lacrimal region5.

Untreated Dacryocystitis never undergoes spontaneous resolution. It tends to progress as wall of the sac become atonic and contents can be evacuated only by the external pressure6. Acute Dacryocystitis may lead to lacrimal abscess. If untreated it may causes unilateral chronic conjunctivitis, corneal ulcer, lacrimal abscess, fistula and panophthalmitis may occur if any intra ocular surgery is performed in presence of unrecognized Dacryocystitis6. Other complications are orbital cellulitis; cavernous sinus thrombosis and orbital thromboplenitis4. Most of the people consider watering from eyes as minor discomfort and avoid themselves from presenting to ophthalmologist as they are unaware of the deleterious complications.

With the extensive search in literature, we haven’t found any study of Dacryocystitis correlated with socioeconomic status. The goal of the present study was to create awareness of chronic Dacryocystitis in view of morbid condition and to correlate it with socioeconomic status. It’s early diagnosis and treatment is always warranted to avoid complications and need for surgical intervention.
Material and Methods
The present study is a cross-sectional hospital based study approved by the ethical committee which performed during the months of June and September, 2014 with written informed consent of the 28 patients in the department of Ophthalmology in a rural tertiary care centre, Dhule, Maharashtra, India.

All patients complaining of watering or discharge through the eyes were included in the study. All patients who had undergone any surgical intervention in the past like dacryocystorhinostomy, and congenital dacryocystitis were excluded from the study.

The present study is a cross-sectional hospital based study approved by the ethical committee which performed during the months of June and September, 2014 with written informed consent of the 28 patients in the department of Ophthalmology in a rural tertiary care centre, Dhule, Maharashtra, India.

</table>

The advantage with Prasad’s classification is that it takes into consideration only the income as a variable and it is simple to calculate. This can be applied to assess the socioeconomic status in both rural and urban areas.

3. Chief Complaints, medical history, treatment history and surgical history were recorded. A detailed present and past medical history was taken which elaborated and helped towards the diagnosis. All the patients were asked and examined for any surgical history in the past.

4. Examination of eyes and adnexa with:
   1. Torch light
   2. Slit lamp
   Thorough detailed examination of eyes and adnexa was performed using diffuse torch light and slit lamp.

5. Regurgitation test and sac syringing
   1. Regurgitation Test: In chronic Dacryocystitis the contents of the sac shall regurgitate through the lower or lower and upper punctum both. In chronic Dacryocystitis with functional block, i.e. pump failure the contents of the sac shall empty in the nose. In chronic Dacryocystitis with encysted mucocele, there is no regurgitation of the contents.
   2. Sac Syringing: This method of exploration was first advocated by Dominique Angel (1716) and then popularized by Bowman in 1857. Thomas R. et al (1997) stressed upon the importance of ROPLAS (Regurgitation on pressure over the lacrimal sac), sac syringing in the diagnosis of chronic Dacryocystitis prior to cataract surgery.

These details were collected prospectively and analyzed retrospectively using SPSS software and conclusion was derived based on observations.

Results
In the present study, majority of cases of chronic Dacryocystitis belongs to the seventh decade of life between age group of 60-70 years (50%). (Table 2)
In our study, chronic Dacryocystitis affected more in females than males (F:M ratio is 2.1:1) as in Table 3.

**Discussion**

Chronic Dacryocystitis though a common problem of lacrimal drainage system, treated much efficiently in recent years with advances in investigative operational technique pertaining to solve the problems associated with it2. Epiphora is the most annoying symptom in about 87% cases, followed by discharge, swelling, pain and conjunctivitis2.

In present study of 28 cases, various modes of presentation of chronic Dacryocystitis cases presented at our institute were taken up for this study during the month of June and September 2014. Patients of chronic Dacryocystitis with respect to their age, sex, occupation and socioeconomic status were studied. The following observations were noted during the course of study with relevant results. These are discussed in comparison with the studies published previously.

Jacobs BH2 in his study found the maximum incidence of this condition between 40-55 years of age. Sarda et al10 noted maximum incidence of chronic Dacryocystitis in the third and fourth decade of life. R. Dalglesh8 stated that 35-40 years was the earliest expected age of onset of acquired idiopathic nasolacrimal duct obstruction. Saxena R.C. and Garg KC11 quoted a maximum age incidence in the fourth decade. Duke Elder S12 states that the disease preferentially affects adults over middle age being relatively rare in children and adolescents. The highest incidence quoted by him was in the fourth decade of life.

Our results show 50% of the patient belongs to seventh decade of life that is between 60-70 years of age.

Jacobs HB2 found a female to male ratio of 3:1 in his series of patients. The reason for females were more affected by chronic Dacryocystitis is due to higher vascular congestive factor and a narrower bony nasolacrimal canal. Our findings were comparable with Jacobs HB2. R. Dalglesh reported a percentage of 54% amongst females8. Saxena R.C. has an incidence of 84.6%11. Duke Elder states that while the disease in the newborn affects both the sexes equally, its occurrence among adults is in the ratio of 75- 80% females to 25-30% male12.
Pawar and Patil\(^1\) had an incidence of 56\% of females in their series of 150 cases of chronic Dacryocystitis. Predilection for the female is due to narrower lumen of the bony lacrimal canal according to Santos Fernandez (1903-21), Heineoneu (1920) Meller (1929), Ruiz Barreranco and Martinoz Roman (1966)\(^4\), Dacryocystitis is more common in temperate climate by True (1900 -1926)\(^1\). Anatomical factor is one of the most common etiological factor of Dacryocystitis as described by Schaeffer (1920). Granstrom (1938) Sonderman (1923) has shown in their studies that constriction of lacrimal duct 40\%, moderate 29\% and 31\% had normal lumen\(^1\). Others Zabel (1900), Onodi (1913), with all (1912), Heinonen (1920) found that narrowing tends to occur in flat nose and narrow face\(^6\). Harmer (1915), Bilancioni (1921) stressed on mechanical obstruction which plays important role in Dacryocystitis. Klofter (1919 -1930), Stenger (1920) described in their studies that septal deviation leads to infection of the lacrimal sac\(^1\).

In our study we found 67\% cases amongst females 33\% cases amongst males with F: M ratio is 2:1:1. In our series of study majority of the wage laborers (35.71\%) were effected followed by farmers (32.14\%). The incidence of 7.14\% of the cases belonged to the petty class families who lack in their cleanliness and scrupulousness in maintaining their eyes clean. Chronic Dacryocystitis is less common among people of urban areas with middle class to rich class who take maximum hygienic measures to maintain their eyes clean.

It is imperative to understand the socioeconomic status (SES) of the community in order to correlate its impact on health quality of living standard. Socioeconomic stratification is the key parameter for proper understanding of the affordability of the community of health services, amenities and their purchasing capacity. When it is taken as a summation of education, occupation and income, it reflects the value system expected for that level\(^9\).

The important determinant of the standard of living is socioeconomic status of the individual/community. SES influences on the incidence and prevalence of various health related conditions. Socioeconomic status also influences social security in terms of the accessibility, affordability, acceptability and actual utilization of various health facilities. The advantage with B.G. Prasad's classification is that it takes into consideration only the income as a variable and it is simple to calculate. This can be applied to assess the socioeconomic status in both rural and urban areas\(^2\).

We haven’t find any study regarding relationship of socioeconomic status with Dacryocystitis by extensive review of literature. In our series, we followed Modified B.G. Prasad classification for categorizing socioeconomic status of the patients, according to which 14 (50\%) patients belongs to class V, 9 (32.14\%) to the class III, 4 (14.28\%) to class IV and only 1 (3.5\%) patient belongs to class II. No patient was belonging to class I.

As per our study, Dacryocystitis was more common in class V & III of socioeconomic status. This might be due to poor hygiene and low living standard of particular socioeconomic class.

**Conclusion**

Dacryocystitis is common eye disease in ophthalmology practice. It is an important cause of ocular morbidity in India. The main cause for chronic Dacryocystitis is obstruction which leads to stasis and altered environment within the lacrimal sac. Most of the people consider watering from eyes as minor discomfort and avoid themselves from presenting to ophthalmologist as they are unaware of further deleterious complications.

With the extensive search in literature, we haven’t found any study of correlation between dacyrocystitis with SES. Therefore this subject needs an extensive study and awareness to solve the enigma of chronic Dacyrocystitis in the people of low socioeconomic group with poor hygiene and low standard of living.
